

Final Findings and Publication Outcome

Publisher: Keddeh Systems | Rights holder: Keddeh Systems (project attribution; legal ownership not independently verified)

Author: OpenAI Codex, technical assessment and document preparation | Architecture and supplied source: Aboudy Keddeh

Classification: Project research | Licence: Reserved rights; no new licence grant

Version: 1.1 | Date: 8 October 2026 (Australia/Adelaide)

Status: Prepared for owner review and publication; no independent approval or certification

Imported source baseline, followed by identified local fixes: Keddeh1/KEDDEH--, commit 29a22dcfdd89d8c7cf90c83d1bda7d7f9a5e37b9

1. Abstract and outcome

This research venture produces three separate technical reports and an evidence bundle tied to a verified repository baseline. The result is an actionable ten-target development programme with reproduced constituent checks and explicit release boundaries. The publication outcome is a reviewable research package, not a declaration that all ten development targets have been implemented.

2. Repository and authorship custody

The supplied archive was imported as 273 files and pushed to Keddeh1/KEDDEH-- main at the baseline commit stated in this document. Reports identify supplied architecture, observed execution and proposed development separately. Codex performed source analysis, local execution and report preparation. No independent reviewer, sponsor acceptance, legal ownership verification or standards certification is invented.

3. Findings by evidence boundary

F01: the engineering invariants are locally exercised by 15 passing tests (E01). F02: the MCP runtime's own self-test passes (E02). F03: the declared Python memory layout is contiguous and internally consistent (E03). F04: native compilation now passes after source corrections; its layout check matches declared dimensions (E04). F05: selected existing WASM operations execute successfully (E05,E06). F06: Rust estate qualification is not established by the unlocated entry in E05. F07: the separately developed control-plane prototype remains outside the imported baseline. Its earlier PGLite test results do not establish independent multi-node PostgreSQL behavior. F08: full workstation startup, remote Chromium/WebRTC recovery, external pool work acceptance and signed rollout have not been reproduced in this venture.

4. Development outcome

T01-T10 specify independent source anchors, work packages and measurable acceptance gates. Highest immediate value comes from reproducible builds, an authoritative inventory, durable ownership, sector supervision and telemetry-backed repair. Native ABI alignment is an early prerequisite, not a late optimization. Browser recovery follows checkpoint and authority integration. Controlled release and rollback close the feedback loop.

5. Publishing package and evidence controls

The package includes Markdown source and print-formatted PDF for each report, original command logs, structured exit-code receipts and the generated current WASM custody receipt. A SHA-256 manifest allows bytes to be checked after transfer. Hashes establish byte identity, not scientific validity. PDF metadata, repeated headers/footers, report IDs, date, version and reserved-rights attribution are included. The skill catalogue lists publishing-standard.md and KEDDEH_Research_Formal_Publishing_Template.docx. Direct reads failed; the catalogue bundle retrieval received proxy HTTP 403. The assets are listed but not retrieved in this execution context. Exact asset-based conformance has therefore not been tested. This is an access and verification boundary, not evidence of a document defect or missing template.

6. Release and approval disposition

The reports are prepared for owner review and publication. They are not signed, independently peer-reviewed or certified. Their engineering claims are publishable with the stated scope and evidence; presenting them as production qualification would exceed the experiments. External website publication and production deployment are separate operations. Repository publication is verified only if a successful Git push is followed by remote readback.

7. Remaining research gates

Obtain a clean full-stack build, repeat concurrency tests on a real shared PostgreSQL primary, implement and validate immutable profile restoration, exercise workstation end-to-end interaction, measure fault recovery, and perform sector canary rollback. Retrieve the catalogued template through its supported bundle route after the network policy permits the listed download host, then compare its requirements and regenerate the package before claiming exact compliance. The absent-artifact status attribution has been corrected; maintain that rejection behavior in subsequent qualification. Each gate has a corresponding T01-T10 specification and can be completed without changing the project identity model.

8. Final determination and references

The source contains substantial executable engineering, MCP and WASM foundations. The research's defensible finding is that coherent self-support requires a bounded control loop around those foundations: observe, decide under authority, act within limits, verify, preserve evidence and escalate unresolved conditions. The programme is sufficiently specified to guide implementation and independent acceptance testing. Integrated production readiness remains an experimental outcome to be demonstrated.

Source references: paths above are relative to the stated GitHub baseline. Evidence E01-E06 is supplied in evidence/ with commands, exit codes and SHA-256 receipts. E05-generated-receipt.json is the current generated receipt; original repository evidence was restored after the test. The separate session-control module is outside the source baseline and is not represented as deployed. Source inspection establishes structure, not operating performance. No third-party literature review, standards certification, live pool share acceptance or deployed recovery experiment is claimed.
