

Publication Conformance: Statement Correction and Technical Disposition

Report ID: RV-P01 | Version: 1.0 | Date: 8 October 2026 (Australia/Adelaide)

Author: OpenAI Codex | Contribution: statement audit, artifact inspection and corrective documentation

Publisher attribution: Keddeh Systems | Rights holder attribution: Keddeh Systems, not independently legally verified

Licence profile: Reserved rights; no additional licence grant | Classification: Project research

Status: Corrective review completed; template comparison awaiting asset retrieval

1. Determination

The sentence “Exact conformity to the unavailable publishing template remains unverified” combined a valid verification limitation with an inadequately supported availability assertion. No comparison with the template had occurred. Calling it unavailable without exhausting the catalogue route overstated the evidence. The corrected finding is that the template is catalogued, but its bytes were not retrieved through the attempted interfaces. No actual template deviation was demonstrated. The statement should not have implied missing source material, defective research or an inherent inability to publish.

2. Provenance and causal sequence

The project publishing skill explicitly requires reading references/publishing-standard.md and using assets/KEDDEH_Research_Formal_Publishing_Template.docx as a layout reference. Previous skills.read calls returned failed-to-read errors for the reference. Those errors explain why exact compliance was not asserted, but do not establish that the files do not exist. The current MCP catalogue lists both assets, the publishing_core.py script and associated graphic resources. Reading the package root exposes an application/gzip bundle download route. Direct child resource reads return Unknown resource. The authorized file-download tool could not resolve the catalogue file identifier. The signed bundle request was then attempted through the inherited proxy and received Tunnel connection failed: 403 Forbidden. No TLS verification was disabled and the proxy was not bypassed.

3. Meaning of conformance

Conformance is a relationship among an identified requirement set, an identified artifact version, a test method and a recorded result. Exact layout conformance could include page dimensions, margins, fonts, colours, masthead, style definitions, header/footer content, pagination fields and spacing. Semantic publishing conformance includes separate author, contributor, publisher, rights-holder, licence, classification, version, status and evidence identifiers. DOCX structural conformance additionally involves style inheritance, section relationships and field codes. PDF validation assesses the rendered output and metadata; it cannot alone demonstrate DOCX-native structure.

A requirement can be observed as satisfied, observed as violated, not applicable with reason, or not evaluated. Not evaluated must not be silently rewritten as violation. A successful checksum check establishes matching bytes, not satisfaction of the publishing rules. A visually coherent PDF does not independently establish conformity to a specific unseen template.

4. Verification actually completed

The original three reports have separate identities, eight numbered body sections, source and evidence references, attributed author/contribution, publisher/rights attribution, reserved-rights wording, date, version and status. Their PDFs were rendered and inspected page by page. Header, footer, page number and readable content were checked. The current revisions are regenerated and checked for those properties again. These are accessible-skill checks and local formatting checks. They are not a substitute for reading the full publishing standard or evaluating the DOCX reference.

No independent peer review, legal approval, standards certification, digital signature or production deployment qualification is inferred. The ten-target programme is a research/development specification; the successful local tests qualify named

constituent operations. Publication compliance and engineering validation remain independently addressable.

5. Responsibility and correction

The authoring agent was responsible for resolving the prerequisite before making an exact-conformance claim, and for describing access errors precisely when it could not resolve them. The requirement itself was not fabricated: it is stated in the supplied publishing skill. The file-unavailability characterization was an unsupported generalization from retrieval errors. The previous final message and the report caveats are superseded by this narrower, evidenced account. The original Git versions remain retrievable; revised reports carry version 1.1 rather than erasing history.

6. Actions executed

The skill was reread, its catalogue and package resource inspected, direct child reads tested, authorized file download attempted, and the bundle download tested through the managed proxy. A draft environment change adds only `sdmntprcentralus.oaiusercontent.com`, preserving the package-manager preset and existing custom policy. Draft persistence was confirmed. This save does not apply runtime changes or publish the environment. The reports now replace the vague availability statement with the specific retrieval and verification boundary. A structured conformance record, this correction report, fresh rendering checks and updated artifact hashes accompany the amended package.

7. Exact remediation after access is applied

Review and save the network addition in environment settings, then publish the environment as required by the configuration tool. Fetch a fresh package-root bundle URL; do not retain or publish signed download URLs. Extract safely and read `publishing-standard.md` and `publishing_core.py` before executing the publishing workflow. Hash and identify the exact template version. Inspect its DOCX section properties, styles, header/footer relationships, field codes, core properties and embedded assets. Convert its normative requirements into individual acceptance checks. Regenerate editable DOCX and PDF reports through the template or its documented publishing API. Render every page, compare against reference properties, inspect layout, verify author/rights/status fields and update the conformance matrix and checksums. Push only after these checks and read back the repository revision. A freshly retrieved template may introduce new requirements; they cannot be invented in advance.

8. Final implication

The resolved logical error concerns certainty of language, not the existence of the architecture or the validity of independently reproduced tests. "Catalogued but retrieval blocked; exact comparison not executed" states the evidence accurately. The current package has documented accessible-rule and rendering checks. Exact proprietary-template comparison remains a concrete, narrowly scoped external prerequisite. Neither a pass nor a failure against that unseen standard is asserted.
